Hand Hygiene

Chapter 10

Hand Hygiene

Carolina Giuffré and Claire Kilpatrick

Key Points

- Hand hygiene is the most effective single measure to prevent transmission of healthcare-associated pathogens.
- Compliance with hand hygiene recommendations is often sub-optimal; compliance is influenced by many factors, including equipment/supplies, time constraints, and behavioural factors.
- Hand hygiene can be performed either rubbing with an alcohol-based hand rub or by washing with soap and water. The World Health Organization recommends the preferred use of alcohol-based hand rub for routine hand hygiene in health care, if available.
- Hand hygiene promotion and multimodal improvement strategies have a great impact on healthcare worker practices and can reduce healthcare-associated infections and the spread of resistant microorganisms.
- Effective strategies include: provision of alcohol-based hand rubs and clean water, soap, and disposable towels; staff education; monitoring of hand hygiene practices and performance feedback; reminders in the work place; and promotion of a patient safety climate.
Background

Hand washing with soap and water has been considered a measure of personal hygiene for centuries. In the mid-1800s, studies by Ignaz P. Semmelweis in Vienna, Austria, and Oliver Wendell Holmes in Boston, Massachusetts, USA, established that hospital-acquired infections were transmitted via the hands of healthcare workers (HCW). Following the observation of high maternal mortality rates due to puerperal fever, Semmelweis made physicians wash their hands in a chlorinated lime solution before every patient contact. Knowledge of the transmission of pathogens through hands and of infection prevention has greatly evolved, and the first international guidelines on hand hygiene published in 2009 recommended a range of evidence-based actions.

Resident or transient microbial flora is present on normal human skin. Resident flora are protective and less likely to be associated with healthcare-associated infections (HAI), however they can cause contamination of sterile body cavities, eyes, or non-intact skin. Transient flora colonise the superficial layers of the skin and may cause HAIs as they are acquired and passed on by HCWs during direct contact with patients or contaminated environmental surfaces. Contaminated HCWs' hands are the commonest route of transmission of HAIs. Hand hygiene is therefore the most effective measure to prevent HAIs.

Hand Contamination

HCWs hands can become contaminated, even if gloved, with pathogens, such as Staphylococcus aureus, enterococci, Clostridium difficile, Gram-negative bacilli, and some viruses (e.g., respiratory syncytial virus and rhinovirus). This can happen by touching patient skin or body sites contaminated or infected with pathogens (known or unknown) including draining wounds, as well as contaminated surfaces within the health care environment, especially surrounding the patient. Some activities in particular can lead to heavier hand contamination and the potential for pathogen spread if the right actions are not taken. Examples include direct patient touch, touching body fluids or waste, diaper change, and respiratory care. In addition, HCWs with dermatitis or skin lesions on their hands may remain colonised with acquired microorganisms for a significant period of time.

Subungual (beneath the nails) areas of the hand carry high concentrations of microorganisms, contributing to the spread of pathogens. Artificial nails may also contribute to the transmission of pathogens as wearers are more likely to harbour Gram-negative bacilli on their fingertips than those with natural nails, despite hand washing or rubbing with an alcohol-based product. Diseased fingernails reduce the efficacy of hand hygiene. The skin underneath rings (including wedding rings) is more heavily colonised than that on other fingers. Rings with sharp and voluminous surfaces and long, sharp fingernails, either natural or artificial, can puncture gloves and limit HCWs’ hand hygiene efficacy.

Compliance Among Healthcare Workers

Without adequate hand hygiene, hand contamination increases; contaminated HCWs’ hands have been associated with endemic HAIs. Therefore, hand hygiene is the primary measure to prevent HAIs and will also help decrease the spread of multidrug resistant microorganisms, thus supporting the current global antimicrobial resistance agenda. However, many determinants, such as lack of time, lack of equipment/supplies, and behavioural factors, often result in HCWs neglecting hand hygiene. Although many HCWs perceive their performance as high, their hand hygiene compliance is usually < 40% in the absence of interventions.

Hand hygiene performance varies according to work intensity, type of ward, professional category, and time of day/week. Compliance can be lower in settings with high care intensity (e.g., intensive care units), among physicians, and before rather than after touching a patient. Indeed, HCWs tend to comply more frequently with indications that protect themselves (e.g., after exposure to body fluids, after glove use, after
Hand Hygiene

contact with the patient or the patient’s environment). This is important in understanding how to affect behaviours and ensure patient safety in relation to HAI prevention.

Products and Techniques

Hand hygiene can be performed either by rubbing with an alcohol-based formulation or by washing with soap and water. Liquid soap is preferred; if there is no other choice, bar, leaf, or powder may be used. Supplies must be placed alongside running water and re-stocked when needed in order to achieve compliance. Plain soap has minimal antimicrobial activity, nonetheless it is recommended for hand washing because mechanical friction alone removes many transient microorganisms. (See Table 10.1)

The commonest antimicrobials in hand hygiene products are: alcohols, chlorhexidine, iodine, and iodophors. Studies suggest efficacy against Gram-positive and Gram-negative bacteria with maximum efficacy is demonstrated by alcohols and iodophors. Mycobacteria and fungi are most effectively eliminated by alcohols, less so by chlorhexidine.

Enveloped viruses (e.g., herpes simplex, human immunodeficiency, influenza, and respiratory syncytial) are highly susceptible to alcohols; hepatitis B and C viruses require high concentrations (70-80% [volume/volume (v/v)]). Alcohols have shown in vivo activity against some non-enveloped viruses (rotavirus, adenovirus, rhinovirus, hepatitis A virus, and enteroviruses). In vitro virucidal activity against surrogate strains of norovirus was demonstrated by 70% alcohol-based formulations. Several norovirus outbreaks were controlled with preventive measures, including use of alcohol-based hand rub. In general, ethanol has greater activity against viruses than isopropanol.

Iodophors and chlorhexidine have some activity against enveloped and some non-enveloped viruses. None of these antiseptics has activity against bacterial spores or protozoan oocysts, although the mechanical effect of washing with soap and water allows their partial removal.

According to the World Health Organization (WHO) alcohol-based hand rubs should be the preferred method for hand hygiene. See Table 10.1 These products have the broadest antimicrobial spectrum, require a short time (20-30 sec) for effective antimicrobial decontamination, have better skin tolerance, and are readily available at the point of care (i.e., where care is provided).

©International Federation of Infection Control
The efficacy of an alcohol-based hand rub depends on its quality, the amount used, the time spent rubbing, and complete coverage of the hands’ surfaces (See Figure 10.2). These parameters also apply to washing with soap and water (See Figure 10.3). Hand rubs containing 60–80% alcohol are satisfactory, provided that they meet recommended standards (European Norms [EN] or American Society for Testing and Materials [ASTM] standards). 1,14 75-87% ethanol, isopropanol, or n-propanol, or a combination of these products guarantee the optimal antimicrobial efficacy. The WHO-recommended formulations contain either 75% v/v isopropanol or 80% v/v ethanol.1,15 There is clear evidence that local manufacture of quality products is possible in low resource settings.16 This formulation is listed in the WHO Essential Medicines List.

It is worth noting that during the Ebola virus disease outbreak of 2014-2015 in West Africa, the use of chlorine for hand washing was prominently featured. Despite some statements that it was part of outbreak control, there is emerging evidence of the harm caused by its over and misuse. WHO published a guideline recommending that due to lack of evidence, health facilities should move to the use of alcohol hand rub and soap and water over the use of chlorine.17

Figure 10.2. Hand hygiene technique with an alcohol-based formulation (Based on the hand hygiene technique with an alcohol-based formulation, http://www.who.int/gpsc/5may/tools/system_change/en/index.html © World Health Organization 2009. All rights reserved.)

Alcohol-based hand rubs are available as rinses (with low viscosity), gels, foams, and impregnated wipes. However, the wipes require more evidence before they can be used effectively in practice.18-20

Points to consider when selecting a product include: 1,15

1) demonstrated antimicrobial efficacy according to ASTM or EN standards for hygienic hand antisepsis and/or surgical hand preparation;
2) proven good dermal tolerance and minimal skin reactions;
3) minimum drying time (products that require longer drying times may affect hand hygiene best practice);
4) cost;
5) aesthetic preferences of HCWs and patients, such as fragrance, colour, texture, “stickiness”, and ease of use; and
6) availability, convenience, and functioning of dispensers, and ability to prevent their contamination.13

©International Federation of Infection Control
A rational location of facilities and supplies (i.e., sinks, soap, towels, and hand rub dispensers), as well as good maintenance and user-friendliness, are essential to facilitate hand hygiene when it is most needed at the point of care. Ideally, different alcohol-based hand rub dispensers, e.g., pocket bottles, wall-mounted, or those placed on carts/trolleys, night stand/bedside table, or affixed to the bed rail, should be used. Confirmation of the need to extend the use of hand rub at the point where care is provided was published by the WHO in its report on water, sanitation and hygiene in health care facilities. It states that 35% of facilities do not have water and soap for handwashing.

There is a misconception that handwashing must be followed by use of an alcohol based hand rub for antisepsis. The recommendation not to do this is clearly featured in the WHO Guidelines and is an important resource efficient consideration.

**Figure 10.3.** Hand washing technique with soap and water (Based on the hand washing technique with soap and water, URL: http://www.who.int/gpsc/5may/tools/system_change/en/index.html © World Health Organization 2009. All rights reserved.)

### When to Perform Hand Hygiene

The “My five moments for hand hygiene” approach (See Figure 10.4) merges the hand hygiene indications into five moments when hand hygiene is required, focused on microbial risk as well as human factors thinking. These are:

1. Before touching a patient,
2. Before clean/aseptic procedures,
3. After body fluid exposure/risk,
4. After touching a patient, and

©International Federation of Infection Control
5) After touching patient surroundings.

This approach proposes a unified vision for HCWs, trainers, and observers to minimise inter-individual variation in practice.

![My 5 moments for hand hygiene](image)

**Figure 10.4.** “My five moments for hand hygiene” (reproduced with permission from reference 12)

**Glove Use**

Gloves are used as personal protective equipment (PPE) to protect HCWs’ hands. They can reduce transmission of pathogens and help control outbreaks as part of PPE recommended use. However, gloves are only effective in prevention of HAI if rigorously accompanied by other measures, including hand hygiene; the use of gloves never negates the need for hand hygiene. To prevent HCW contamination, gloves must also be used according to established indications for donning and removal.

Use of the same gloves for several hours, while providing care to different patients and touching multiple surfaces, is a very frequent malpractice. Several studies have established an association between inappropriate glove use and low compliance with hand hygiene. Others have found that HCWs wearing gloves were significantly more likely to cleanse their hands following patient care.25,26

Understanding that glove use does not replace hand hygiene is of utmost importance. When there is a need for performing hand hygiene (opportunity) before a care act which also requires glove use (indicating Moment 2 of the WHO 5 Moments), hand rubbing or handwashing must be performed before donning gloves, as well as immediately after glove removal.27 Within the ‘patient zone’ if a Moment 2 or 3 arises, whether gloves are worn or not, hand hygiene should be performed, with removal of gloves at these times.28-30

**Improvement Strategies**

Key components of successful strategies are:

**System change**

Ensure that the necessary infrastructure is in place to allow HCWs to practice hand hygiene. This includes two essential elements:

1) provision of alcohol-based hand rub at the point of care; and
2) access to a safe, continuous, water supply, soap, and disposable towels.

**Training/education**

Provide regular training on microbial transmission through HCWs’ hands and the importance of hand hygiene based on the "My five moments for hand hygiene" approach. Also include the correct procedures for hand rubbing and hand washing by using real life clinical scenarios in presentations, e-learning modules, posters, focus groups, reflective discussion, videos, self-learning modules, practical demonstrations, feedback from assessment, buddy systems, or combinations of these methods. Assess the impact of training on HCWs’ knowledge to identify areas for further education.

**Evaluation and feedback**

Monitor hand hygiene practices and knowledge among HCWs and provide results to staff. The gold standard for measuring hand hygiene compliance remains direct observation; electronic monitoring of hand hygiene actions and evaluation of alcohol-based hand rub consumption can be used as indirect methods and surrogate markers. The applicability of electronic systems needs serious consideration given the associated costs and the actual potential for behaviour change. Use of the WHO Hand Hygiene Self-Assessment Framework provides a score to use for evaluating facility progress with hand hygiene improvement.

**Reminders in the workplace**

Remind HCWs about the importance of hand hygiene and the indications and procedures for performing it. Change these prompts on a regular basis to continue to have an impact on behaviour.

**Institutional safety climate**

Create an environment that raises awareness about patient safety while making hand hygiene a high priority at all levels, including active participation at institutional and individual levels.

Elements of this multimodal strategy to improve hand hygiene demonstrated reduction in HAI and cross-transmission rates of potential pathogens. Multimodal interventions are considered most effective for compliance.

It has become increasingly clear that hand hygiene is a behaviourally driven science. Hand hygiene is a modifiable behavioural risk factor for HAI. Goal setting, award incentives, and accountability have recently been highlighted as important elements of achieving a safety climate. Addressing different combinations of interventions is deemed important. Human factors could play a role in behaviour change and compliance if the IPC community engages with other disciplines such as social sciences.

**Summary**

HCWs’ hands play a crucial role in the transmission of microorganisms during the sequence of care and contact with environmental surfaces and patients’ skin. Hand hygiene is the single most effective measure to prevent HAI. However, hand hygiene practice at the right moment using proper technique is usually sub-optimal among HCWs due to many perceived constraints and behavioural factors. Improvement of practices can be achieved and lead to substantial reduction of HAI by multimodal behaviour change strategies aimed at strengthening infrastructure, knowledge, and the institutional patient safety culture. Hand hygiene is not ed as one of the Top Patient Safety Strategies that can be encouraged for adoption. The preferred use of alcohol-based hand rubbing as the gold standard for hand hygiene and the identification of the right moments for hand hygiene during patient care are essential elements for success.

**Table 10.1. World Health Organization Consensus Recommendations Hand Hygiene in Health Care, 2009**

**Recommendation by topic and grade according to the HICPAC ranking system***

1. **Indications for hand hygiene**
   A. Wash hands with soap and water when visibly dirty or visibly soiled with blood or other body fluids (IB) or after using the toilet (II).
   B. If exposure to potential spore-forming pathogens is strongly suspected or proven, including outbreaks of *C. difficile*, hand washing with soap and water is the preferred means (IB).
   C. Use an alcohol-based handrub as the preferred means for routine hand antisepsis in all other clinical situations described in items D(a) to D(f) listed below if hands are not visibly soiled (IA). If alcohol-based handrub is not obtainable, wash hands with soap and water (IB).
   D. Perform hand hygiene:
      a) before and after touching the patient (IB);
      b) before handling an invasive device for patient care, regardless of whether or not gloves are used (IB);
      c) after contact with body fluids or excretions, mucous membranes, non-intact skin, or wound dressings (IA);
      d) if moving from a contaminated body site to another body site during care of the same patient (IB);
      e) after contact with inanimate surfaces and objects (including medical equipment) in the immediate vicinity of the patient (IB);
      f) after removing sterile (II) or non-sterile gloves (IB).
   E. Before handling medication or preparing food perform hand hygiene using an alcohol-based handrub or wash hands with either plain or antimicrobial soap or water (IB).
   F. Soap and alcohol-based handrub should not be used concomitantly (II).

2. **Hand hygiene technique**
   A. Apply a palmful of alcohol-based handrub and cover all surfaces of the hands. Rub hands until dry (IB).
   B. When washing hands with soap and water, wet hands with water and apply the amount of product necessary to cover all surfaces. Rinse hands with water and dry thoroughly with a single-use towel. Use clean, running water whenever possible. Avoid using hot water, as repeated exposure to hot water may increase the risk of dermatitis (IB). Use a towel to turn off tap/faucet (IB). Dry hands thoroughly using a method that does not recontaminate hands. Make sure towels are not used multiple times or by multiple people (IB).
   C. Liquid, bar, leaf or powdered forms of soap are acceptable. When bar soap is used, small bars of soap in racks that facilitate drainage should be used to allow the bars to dry (II).

3. **Recommendations for surgical hand preparation**
   A. Remove rings, wrist-watch, and bracelets before beginning surgical hand preparation (II). Artificial nails are prohibited (IB).
   B. Sinks should be designed to reduce the risk of splashes (II).
   C. If hands are visibly soiled, wash hands with plain soap before surgical hand preparation (II). Remove debris from underneath fingernails using a nail cleaner, preferably under running water (II).
   D. Brushes are not recommended for surgical hand preparation (IB).
   E. Surgical hand antisepsis should be performed using either a suitable antimicrobial soap or suitable alcohol-based handrub, preferably with a product ensuring sustained activity, before donning sterile gloves (IB).
   F. If quality of water is not assured (as described in Table I.11.3) in the operating theatre, surgical hand antisepsis using an alcohol-based handrub is recommended before donning sterile gloves when performing surgical procedures (II).
   G. When performing surgical hand antisepsis using an antimicrobial soap, scrub hands and forearms for the length of time recommended by the manufacturer, typically 2–5 minutes. Long scrub times (e.g. 10 minutes) are not necessary (IB).
   H. When using an alcohol-based surgical handrub product with sustained activity, follow the manufacturer’s instructions for application times. Apply the product to dry hands only (IB). Do not combine surgical hand scrub and surgical handrub with alcohol-based products sequentially (II).
   I. When using an alcohol-based handrub, use sufficient product to keep hands and forearms wet with the handrub throughout the surgical hand preparation procedure (IB).
   J. After application of the alcohol-based handrub as recommended, allow hands and forearms to dry thoroughly before donning sterile gloves (IB).
